

The functions `some` and `many` are defined in terms of each other.

~~This is the same principle as~~
This is achieved by mutual recursion, which is the same principle behind `odd` and `even`:

`even :: Int → Bool`

`even 0 = True`

`even n = not (odd (n-1))`

`odd :: Int → Bool`

`odd 0 = False`

`odd n = not (even (n-1))`

We could understand this by simply following the definitions. We can also inline:

`even 0 = True`

`even n = not odd (λ x →`

case ~~x~~ of

`0 → False`

`m → not (even m-1))`

We want to understand $\langle \$ \rangle$ and $\langle * \rangle$, since they are used often in parser combinators.

Remember `map` and `fmap`:

$$\begin{aligned} \text{map} &:: (a \rightarrow b) \rightarrow [a] \rightarrow [b] \\ \text{fmap} &:: (a \rightarrow b) \rightarrow f a \rightarrow f b \end{aligned}$$

Let's compare this with $\langle \$ \rangle$

$$\langle \$ \rangle :: (a \rightarrow b) \rightarrow f a \rightarrow f b$$

This allows us to write

$$f \langle \$ \rangle xs$$

instead of

$$\text{fmap } f \text{ } xs$$

New compare ($\langle \$ \rangle$) with ($\langle * \rangle$):
(this time, I won't hide the class constraints)

$\langle \$ \rangle :: \text{Functor } f \Rightarrow (a \rightarrow b) \rightarrow f a \rightarrow f b$

$\langle * \rangle :: \text{Applicative } f \Rightarrow f (a \rightarrow b) \rightarrow f a \rightarrow f b$

We had several instances of ($\langle * \rangle$) defined in the last lecture, we're now ready for the ($\langle * \rangle$) for Parser.

instance Functor Parser where

$$\text{fmap } f (\text{Parser } p) = \text{Parser } (\lambda ts \rightarrow \underbrace{[(ts', f x)]}_{\text{String} \rightarrow [(\text{String}, a)]} \mid (ts', x) \leftarrow p \text{ ts})$$

This creates a new parser where the parsed values are transformed by the function f .

instance Applicative Parser where

-- pure :: $a \rightarrow \text{Parser } a$

pure $x = \text{produce } x$

-- ($\langle * \rangle$) :: $\text{Parser } (a \rightarrow b) \rightarrow \text{Parser } a \rightarrow \text{Parser } b$

Parser pf $\langle * \rangle$ Parser px =

$$\text{Parser } (\lambda ts \rightarrow [(ts'', f x) \mid (ts', f) \leftarrow \text{pf } ts, (ts'', x) \leftarrow \text{px } ts'])$$

The result of Parser pf $\langle * \rangle$ Parser px
is a bit like this:

$f x$ will be the value of type b
 ts'' is what is left over

Let's look at the type of some
more closely:

some $:: \text{Parser } a \rightarrow \text{Parser } [a]$

some $v = (:) \langle \$ \rangle v \langle * \rangle \text{many } v$
